INTRODUCTION

The purpose of this circular is to present a series of brief summaries of the essential average storage requirements of most of the more important varieties of fresh fruits, vegetables, cut flowers, and certain other perishable commodities which enter the market on a commercial scale. Many details are of necessity omitted, as the work is intended primarily for general practical reference. The conditions given should not be considered as absolute or final, but rather as the safe limitations under which the various products can ordinarily be stored. Detailed information on the handling and storage of some of the commodities discussed is available elsewhere

in the form of bulletins or textbooks; for many of them only general information exists.

Fresh fruits, vegetables, cut flowers, etc., intended for storage should be as free as possible from skin breaks, bruises, and decay. They should be neither immature nor overmature, because in either case it may be difficult to keep them from too rapid deterioration, and even if they do not change appreciably in storage, they will not be commercially desirable when removed. The proper degree of maturity in each case can usually be determined by consulting the various sections of this circular or the other publications listed in Literature Cited (p. 40), or on the basis of previous experience. There is a seasonal variation, however, in the storage quality of certain products, particularly fruits; hence care must be taken not to assume too much from one year's experience concerning the probable behavior of a given commodity grown the next year.

Decay and other deterioration in storage is too broad a subject to be discussed in detail in this publication. It is discussed very generally in connection with various fruits and vegetables covered by this circular and in greater detail in other publications (3, 4, 9, 17, 19, 21, 24, 34, 36, 37, 38, 39, 40, 45, 48, 54, 56).¹

FACTORS INVOLVED IN COLD STORAGE

Details of the best conditions for the storage of fresh fruits, vegetables, and cut flowers are subject to change from time to time as more definite information is gained in the handling of these commodities. The conditions and requirements given in this circular are derived from the best commercial practice at the present time and from scientific experimentation.² All of the temperature requirements are given in degrees Fahrenheit and represent the average air temperatures that should be maintained. The humidities are relative and are expressed in percentage of saturation; for example, when it is stated that a certain humidity should be 85 percent, this means that the air should be at approximately 85 percent of complete saturation with water vapor at the recommended temperature.

The term "cold storage" refers to storage where the desired temperature is maintained by mechanical means; the term "common storage" is used where the natural outdoor temperature, modified or controlled as far as possible by means of insulated walls and ventilators, is depended upon to maintain the desired storage temperature. The storage period given in each case includes the transit period if there is one. Allowance has been made for the fact that the temperature of fruits and vegetables in transit is usually higher than the recommended storage temperature and that, except during winter weather, ripening or other changes are likely to go on more rapidly during a given transit period than during the same length of time in cold storage.

TEMPERATURE OF STORAGE ROOMS

If the best results are to be obtained in the cold storage of the products discussed herein it is highly important that the tempera-

¹ Italic numbers in parentheses refer to Literature Cited, p. 40.

² The writers have not only included results of their own investigations but have drawn freely on published and unpublished results of other staff members, whose assistance and cooperation have done much to make this publication possible. Information is also cited from other sources.

ture in storage rooms be held fairly constant. Variations of 2° or 3° above or below the desired temperature are in most cases too large. They can usually be avoided if the storage rooms are well insulated throughout and are furnished with adequate refrigeration and equipped either with reliable, accurate thermostats or with means for manual control which are given frequent personal attention by someone charged with that duty. Even when reliable automatic controls are used, periodic visits to storage rooms should be made by some responsible person.

In commercial cold-storage rooms thermometers are usually placed at about the level of the eyes of a man of ordinary height, sometimes slightly lower. It is important, however, to take temperatures frequently at the floor and the ceiling also, or at any other places where they might be expected to be undesirably high or low. If the air in certain locations seems always to be too warm or too cold it may be necessary to install fans to increase the rate of air movement and so bring about a better equalization of the temperature in various parts of the room.

Most varieties of apples keep best and longest if held constantly at 31.5° to 32° F.; the best temperature for Bartlett pears is between 30° and 31° . If the air temperature where either of these fruits is stored rises 2° or 3° above the upper limit mentioned, there is danger of increased decay and undue ripening, the danger being greater the longer the period during which the temperature is above 32° . For example, 3 or 4 days at 35° usually would have little or no effect, partly because of a slower rise in the temperature of the fruit than in that of the air; but 10 days at this temperature would probably shorten the life of the fruit by about a week and possibly result in more decay. On the other hand, if the temperature goes a degree or two below 30° , there is a chance that freezing will occur. Celery and cabbage allowed to remain too warm in storage may show yellowing and decay; potatoes are likely to begin to sprout if the temperature is too high and usually become undesirably sweet if it is too low. Other commodities undergo these or other kinds of deterioration if the temperature variations throughout long storage periods exceed the limits given for them in this circular. In addition, there is always the possibility that fluctuations in temperature will cause condensation of moisture on stored products, which in itself is undesirable because it favors the growth of mold and the development of decay.

Control of temperature is usually easier in large rooms than in small ones if both are filled to capacity. This is because of the "flywheel" effect produced by the larger mass of material, including both the commodity and the building material. Refrigeration is thus stored up, so to speak, and temperature changes occur more slowly. For this reason small storage rooms generally will require closer attention than large ones.

HUMIDITY OF STORAGE ROOMS

The relative humidity of the air in storage rooms has a direct relation to the keeping quality of the products held in them. If it is too low, wilting is likely to occur in most fruits, vegetables, cut flowers,

etc.; if it is too high, it favors the development of decay, especially in rooms where there is considerable variation in temperature. The exact control of humidity is rather difficult, however, and is not often attempted in commercial storage warehouses. Operators of certain large cold-storage houses have found that when a room is filled with apples or celery, for example, the relative humidity soon becomes constant at a fairly definite level which fortunately is about the optimum for the particular commodity concerned. The same result has been observed with other commercially important fruits and vegetables and probably is obtained in many of the larger, well-constructed cold-storage warehouses of the country.

For most fruits that are stored commercially the general statement can be made that a relative humidity of 80 to 85 percent gives the best results. Exceptions are discussed in the text. For leafy vegetables and root crops the relative humidity should be about 90 to 95 percent; for other vegetables, except as noted in the text, 85 to 90 percent. If it seems necessary to increase the relative humidity in rooms used for common or air-cooled storage, this can best be done by sprinkling the floor occasionally. Earth floors are more desirable in air-cooled storages than floors of concrete because they are more easily kept damp. Usually an increase in air circulation calls for an increase in relative humidity.

Various methods have been proposed or tested for the control of humidity in cold-storage rooms, but at present there seems to be no general agreement among operators of cold-storage plants as to which is the best of these methods, nor has there been widespread use of any of them.

EVOLUTION OF HEAT BY COMMODITY

In any consideration of the storage of fresh fruits and vegetables, cut flowers, etc., it should be remembered that these commodities are alive and that by virtue of that fact they carry on within themselves many of the processes characteristic of all living things. Unless the relative humidity is high, they give off moisture to the surrounding air and most of them, in time, become shriveled or wilted, even at 32° F. The enzymes or ferments they contain act on various substances in their tissues and gradually bring about changes in color, texture, and chemical composition which mature the commodity and may result in serious deterioration or even complete break-down. The most important of these changes are produced by respiration, the process in which the oxygen of the air is combined with the carbon of the plant tissues, occurring chiefly in sugars, to form various decomposition products and eventually carbon dioxide and water. During this process energy is released in the form of heat, the amount of which varies with the commodity and increases as the temperature increases, up to about 100°. This heat is always a part of the refrigeration load which must be considered in handling fruits, vegetables, and cut flowers in cold-storage rooms or refrigerator cars. The approximate rate of evolution of heat by various commodities is given in table 1.

² Unpublished work on the respiration of vegetables by R. C. Wright and T. M. Whiteman.

It will be noted that lettuce, Bartlett pears, peaches, and cherries have a much higher respiration rate than potatoes, apples, and onions. This means that the first group requires considerably more refrigeration than the second to keep them at a specified temperature. Less pronounced differences occur between other commodities in the list and are important to a lesser degree in determining the amount of refrigeration necessary to cool them and keep them in sound, usable condition.

It is difficult to determine the heat to be removed in cooling fruits and vegetables to cold-storage temperatures. This depends mainly on the following factors: The specific heat of the product, the rate at which it produces heat (by respiration), and its initial and final temperature. If the product could be cooled to the storage temperature instantaneously, the heat to be removed would be only the number of British thermal units (B. t. u.) or calories obtained by multiplying the specific heat of the product by the difference between the initial and the final temperature, and this result by the weight of the product in pounds or kilograms. This is usually called the sensible heat. The cooling process, however, requires time, and during this interval additional heat is produced by the respiration of the stored fruit or vegetable.

In order to determine the amount of this additional heat it is necessary to know the rate of heat production at any temperature and the length of time the product is in each temperature range. For example, if the respiration rate (or rate of heat production) for a given commodity is twice as great at 70° F. as at 50°, the number of hours this commodity is at each of these temperatures must be known before the total heat produced can be calculated. When fruits and vegetables cool, the rate at which they produce heat decreases, and the total heat produced depends not only upon the time required for cooling but also upon how long the commodity stays in each temperature range.

Table 2 shows the approximate amounts of sensible heat and of heat produced by respiration which must be removed from seven varieties of four kinds of fruit in cooling them from various tempera-

tures to a temperature of 35° F. These figures are based on experimental determinations of the rate of respiration at various temperatures; some of the data are from the tables given by Magness et al. (24, 26), and the remainder from data reported by Haller et al. (15). The figures for Bartlett pears are based on the maximum values given by Magness et al. (26). The figures given in this table have been obtained by assuming that the heat of respiration is produced by oxidation of a hexose sugar, and can be calculated from the rate of production of carbon dioxide which has been determined experimentally; very few calorimetric measurements of heat production by fruits and vegetables have been made, and this assumption seems to be the best available basis for calculating heat production at any given temperature.

TABLE 2.—*Approximate amounts of heat of respiration and sensible heat to be removed from certain fruits in cooling them from 60°, 70°, or 80° to 35° F. in a room at 32° F., when the cooling takes place in 3, 4, 5, 6, 8, or 10 days*

[Heat expressed in B. t. u. per ton of fruit]

¹ For any one kind of fruit at a given temperature these figures are assumed to be the same for all cooling periods included in the table.

The assumption has also been made, although it is believed to be only approximately correct for fruits and vegetables, that the rate of temperature drop at any given time during cooling is proportional to the difference between room temperature and fruit temperature at that time. With this assumption as a basis, the temperature and thus the rate of respiration at any time during the cooling period, as well as the total heat produced during the whole cooling period, have been calculated.³

As a result of these calculations it has been found that the heat produced by the respiration of fruit while it cools is directly proportional to the length of the cooling period. The figures for cooling periods of 3, 4, 5, 6, and 8 days are therefore set at 3, 4, 5, 6, and 8 tenths (to the nearest thousand) of the figure for 10 days. The specific heat has been calculated by the formula $S=0.008$

³ The authors wish to acknowledge the valuable assistance given by W. V. Hukill, of the Bureau of Agricultural Engineering, in making the calculations and in preparing this statement on the production of heat by fruits and vegetables.

$a+0.20$ in which S signifies the specific heat of a substance containing a percent of water; 0.2 is the value which has been assumed to represent the specific heat of the solid constituents of the substance in question (40).

Column 1 of table 2 shows the kind and variety of fruit and column 2 the temperature of the fruit at the time cooling starts, in a room held at 32° F. The next column shows the amount of heat evolved by respiration if the fruit reaches 35° at the end of 3 days. The next five columns show the amount of heat if cooling to 35° requires 4, 5, 6, 8, or 10 days, respectively. The last column is the sensible heat (obtained by multiplying the specific heat of the fruit by the difference between initial and final temperatures and this result by the number of pounds in a ton). For any one kind of fruit at a given initial temperature, the specific heat is assumed to be the same for all the cooling periods included in the table.

The values given in table 2 are only approximate. The two assumptions that have been made—namely, (1) that the heat of respiration is produced only by the oxidation of a hexose sugar and can be computed from observed amounts of carbon dioxide produced, and (2) that the rate of temperature drop is always proportional to the difference between fruit temperature and room temperature—probably lead to fairly accurate results; but since only a few direct measurements of the heat produced by fruits and vegetables have been made, it is not known just how close the approximation is. The figures are presented to help cold-storage-plant operators estimate the quantity of refrigeration required for cooling the specified fruits under the various conditions given. As an example of how the figures can be used, the following calculation may be of interest: A ton of Bartlett pears cooling from 70° to 35° F. in 10 days in a 32° room is shown to be capable of producing about 54,000 B. t. u. Its sensible heat at 70° (35° above its final temperature) is 61,000 B. t. u. The sum of the two is 115,000 B. t. u. If this be multiplied by the capacity of the room in tons of fruit, say 600 (the capacity of some of the commercial cold-storage rooms in the United States) and divided by 288,000 (the number of British thermal units in a ton of refrigeration), the quotient 239 is obtained; this is approximately the number of tons of refrigeration required to cool 600 tons of Bartlett pears to 35° in 10 days under the conditions specified. The corresponding figure for Winesap apples is 177 and that for Grimes Golden apples, 200.

EFFECT OF COLD STORAGE ON SUBSEQUENT BEHAVIOR OF FRUITS AND VEGETABLES

The belief is rather common among those concerned with the marketing of fresh fruits and vegetables that commodities of this kind that have been in cold storage deteriorate more rapidly after removal from the low temperature than if they had been held at ordinary temperatures. It is difficult, however, to find a basis for judging whether or not they actually do so because there is no means known other than the use of low temperature for checking the ripening and decay so largely responsible for their deterioration—that is, it is impossible in the present state of knowledge to obtain fruits and vegetables that have not been refrigerated but still have not changed in any way since harvest, for comparison with similar lots that have been in cold storage and are eventually removed.

It might be thought that respiration could be used as a basis for judging the effects of cold storage on fruits and vegetables, since this process is one of the important factors in bringing about deterioration. Certain starchy products such as potatoes and bananas that have been held in cold storage respire more rapidly after removal; they produce more carbon dioxide and give off more heat than those which have been held at ordinary temperatures. However, so far as can be discovered, fruits such as peaches, strawberries, oranges, grapefruit, and apples do not. In the case of potatoes and bananas, the reason is thought to be that when these commodities are held at low temperatures, sugar accumulates in their tissues; then when they are removed to higher temperatures, this sugar is readily respired, so that they produce more carbon dioxide and give off more heat than similar lots that have been held continuously at 50° to 60° F. With potatoes, however, the criterion used does not necessarily mean more rapid deterioration. That is, the increase in respiration is not necessarily accompanied by wilting, decay, or discoloration of the flesh.

It can be stated that for many fruits and vegetables, as far as is now known, cold storage at 32° F. is beneficial. Important exceptions are bananas, sweetpotatoes, tomatoes, cucumbers, melons, and certain other horticultural products mentioned herein, the behavior of all of which in storage is discussed later under appropriate headings.

SWEATING

When fruits or vegetables are removed from a low temperature to a higher one there is frequently a condensation of moisture from the air on the cool surface of the commodity. This is known as sweating and is more marked the higher the relative humidity of the outside air. It should be prevented whenever possible in the case of onions and the more tender fruits, because it favors the development of decay. This does not mean that when any of these products sweat after removal from an iced refrigerator car or a refrigerated room they are sure to decay; it does mean that they are more likely to decay than if they were dry after being unloaded and remained dry until consumed. In this connection dryness means merely the absence of liquid water on the surface.

Sweating can be prevented to some extent, as in the British practice with eggs and certain other commodities, by allowing the fruits or vegetables to warm up gradually. Under commercial conditions in the United States this is rarely practicable, however, and the best thing to do in very damp weather is to realize the risk, handle the product carefully, and get it into consumption without undue delay.

The storage conditions recommended herein for certain commodities represent either a compromise between two undesirable extremes of temperature or humidity or a choice of the least harmful of two such extremes. Grapefruit, for example, suffer less from decay at low humidities than at high; on the other hand, at low humidities they are subject to a pitting which is usually more damaging to the market value of the fruit, because it is more common under commercial conditions than is decay. Therefore, it is recommended that grapefruit in storage be held at about 85 percent relative humidity.

On account of the danger of soggy break-down (34) in Grimes Golden apples grown under certain conditions, it is sometimes advisable to store this variety at 34° or 36° F. rather than at 32°. The Jonathan variety suffers less from soft scald if stored at 34° to 36° instead of at 32°. It is susceptible, however, to the more common and more serious condition known as "internal break-down" if held continuously at temperatures above 32°; hence this latter temperature should usually be chosen as safer than any higher one.

FRUITS AND NUTS

By DEAN H. ROSE, *senior physiologist*

The recommended temperature, relative humidity, and approximate length of storage period for the commercial storage of fresh, dried, and frozen fruits, and nuts are given in table 3. Detailed descriptions of these requirements are given in the text following.

TABLE 3.—*Recommended temperature, relative humidity, and approximate length of storage period for the commercial storage of fresh, dried, and frozen fruits, and nuts*

Commodity	Temperature	Relative humidity	Approximate length of storage period	Average freezing point ¹
	° F.	Percent		° F.
Apples.....	31 to 32	85 to 88(2).....	28.4
Apricots.....	30 to 32	80 to 85	10 days.....	28.1
Avocados.....	40 to 55	85 to 90(2).....	27.2
Bananas.....	(2)	(2)do.....	(2)
Blackberries.....	31 to 32	80 to 85	7 to 10 days.....	28.9
Cherries.....	31 to 32	80 to 85	10 to 14 days.....	(2)
Coconuts.....	32 to 35	80 to 85	1 to 2 months.....	25.5
Cranberries.....	36 to 40	85 to 90	1 to 4 months.....	27.3
Dates.....	(2)	(2)(2).....	-4.1
Dewberries.....	31 to 32	80 to 85	7 to 10 days.....	-----
Grapefruit.....	(2)	85 to 90	6 to 8 weeks.....	28.4

Frozen fruits.....	(2)	(2)	6 to 12 months.....	-----
Nuts.....	32 to 50	75 to 80	8 to 12 months.....	(2)

¹ These figures are based on previously published work by Wright (58) and are subject to revision whenever further investigation makes this necessary.

² See text.

³ The figures for bananas are: Green—flesh 30.2° F., peel 29.8°, ripe—flesh 26.0°, peel 29.4°; for cherries: eastern, sour 28.0°, sweet 24.7°, California, sweet 24.2°; for oranges: flesh 28.0°, peel, 27.4°; for pears: Bartlett 28.5°, Winter Nelis 27.2°, Anjou 26.9°; for Persian (English) walnuts 20.0°, pecans 19.6°, and chestnuts (Italian) 23.8°.

APPLES

(Temperature, 31° to 32° F.; relative humidity, 85 to 88 percent)

There is a wide variation in the storage quality of the different varieties of apples, and of the same variety grown in different regions. For example, McIntosh grown in the Middle Atlantic States is practically an early fall apple not suitable for more than a few days' storage, whereas if grown in northern New York or New England it can be held for as long as 4 months. Such varieties as

Northern Spy, Baldwin, and Rhode Island Greening grown in the Cumberland-Shenandoah Valley district or in the hot, irrigated valleys of the Pacific Northwest are very short-lived in storage, although suitable for all-winter storage when grown in New England, New York, Michigan, and other northern producing districts.

The keeping quality of apples in storage is also definitely related to the cultural and orchard sanitation practices of the grower, who alone is responsible for the production of sound, properly matured fruit. To have good keeping quality, apples should be fully grown and well-colored. When they have reached this stage, they are less likely to scald in storage and are in better condition generally to be held in storage for the maximum period than if they are either immature or overmature.

To insure soundness and good keeping quality, apples must be not only properly grown and at the proper stage of maturity, they should also be handled in all the operations of picking, grading, packing, and hauling with that degree of care necessary to prevent serious bruising, skin punctures, or other mechanical injuries; and they should be stored as quickly as possible after they are picked.

Apples intended for storage should not be handled while frozen, if such handling can possibly be avoided. Water core does not develop or spread in storage, and in varieties such as Yellow Newtown and Winesap it may actually disappear after a few months' storage, especially if present only in a mild form. When large portions of the flesh are affected, especially in soft-textured varieties like Jonathan, Delicious, Stayman Winesap, and Rome Beauty, there is danger of subsequent break-down, and prompt disposal of the fruit is advisable. The diseases of apples in storage are discussed in Farmers' Bulletin 1160 (4) and Miscellaneous Publication 168 (37).

For the storage of most varieties of apples the best results are obtained by maintaining a temperature of 31° to 32° F., and a relative humidity of 85 to 88 percent. Yellow Newtown apples from the Pajaro Valley, Calif., should be held at 35° to 38° rather than at 32°, to prevent the development of internal browning or brown core. Grimes Golden apples that are intended for early marketing should be held at 35° to 38° instead of at 32°, in order to obtain better quality and avoid soggy break-down.

If air-cooled storage is used, the temperature obtainable will usually not be much lower than the average of the prevailing outside temperatures. The nearer this is to 32° the better.

The length of time apples can be held successfully in cold storage will vary with the variety, with the district where grown, as well as with their condition when harvested. The following data show about how much time different varieties, as grown in regions to which they are best adapted, require to reach full eating-soft condition when picked at proper maturity and stored immediately at 32° F.

Variety	Months	Variety	Months
McIntosh.....	2 to 4	Rome Beauty.....	5 to 6
Grimes Golden.....	2 to 4	Baldwin.....	5 to 7
Jonathan.....	3 to 4	Rhode Island Greening.....	6 to 7
Tompkins King.....	4 to 5	Stayman Winesap.....	6 to 7
Northern Spy.....	4 to 6	Arkansas.....	6 to 7
Esopus Spitzenburg.....	4 to 6	York Imperial.....	6 to 7
Ben Davis.....	5 to 6	Yellow Newtown.....	6 to 8
King David.....	5 to 6	Winesap.....	7 to 8
Delicious.....	5 to 6		

However, "full eating-soft condition" is not what is wanted in apples withdrawn from storage for sale to retailers and by them to the consumer. The dealer would ordinarily require 2 days to a week for disposing of such apples. In determining when to remove apples from storage he must, of course, consider the market, but he must also allow for the more rapid softening that takes place at the higher temperatures to which they will usually be removed.

Investigations by the United States Department of Agriculture (26) have shown that apples soften approximately twice as fast at 70° as at 50° F., twice as fast at 50° as at 40°, and about twice as fast at 40° as at 32°. It is advisable, therefore, to consider the safe storage period, that is, the period which is safe from the commercial point of view, as about 2 weeks to a month shorter than those given in the tabulation above.

Apples in cold storage should be inspected frequently, in order that they may be removed and sold while still in good condition. It is highly desirable that apples intended for storage be wrapped in oiled paper or packed in shredded oiled paper, in order to reduce damage by scald as much as possible (3). Apples should not be stored in the same room with potatoes because of the danger that the former will absorb undesirable odors (4).

APRICOTS

(Temperature, 30° to 32° F.; relative humidity, 80 to 85 percent)

Apricots picked at a stage of maturity that gives them good varietal sweetness and flavor can be held satisfactorily at 30° to 32° F. for about 10 days. After such storage and a period of 4 days at room temperature they ripen without discoloration, to a desirable texture and flavor. If stored at higher temperatures, they are likely to become tough and flat in flavor after ripening at room temperature, or they may become mealy and develop a stale flavor.

A relative humidity of 80 to 85 percent is recommended for apricots in storage.

AVOCADOS

(Temperature, 40° to 55° F.; relative humidity, 85 to 90 percent)

Investigations in California (29) on the storage of avocados have shown that the best temperature for all varieties grown there, except the Fuerte, is about 40° F. The Fuerte discolors internally at this temperature but holds up well at 45°. At temperatures below 40° all the varieties investigated are likely to become discolored internally and do not soften when removed to a higher temperature.

When properly stored, the Dickinson, Royal, Taft, and Queen are said to hold up well for about 2 months, the Spinks, Sharpless, and Challenge for 5 to 6 weeks, and the Ray, Fuerte, and Kist for about 4 weeks. Most of these varieties are of the Guatemalan race.

No general recommendations can be made concerning the storage of varieties of avocados grown in Florida, Central America, or the West Indies, because of the wide variation among them in susceptibility to injury by low temperatures. Many varieties of the West Indian race are injured by exposure to a temperature of 53° F. for 15 days (49, 50), whereas those of the Guatemalan race are more resistant to cold and those of the Mexican race the most resistant of all. Some of the varieties that are least affected by cold can safely be held at 40° for 30 to 40 days or even longer.

For shippers, receivers, or cold-storage men who must deal with avocados from Florida, Central America, or the West Indies probably the best procedure is to handle commercial lots on the basis of facts determined by their own experience with the particular varieties concerned.

At the higher temperatures mentioned above, anthracnose, a fungus disease of avocados, will probably be an important factor in the storage of this fruit. At the lower temperatures decay is not likely to be troublesome except after long storage.

BANANAS

(Temperature, ripening, 62° to 70° F.; holding ripe fruit, 56° to 60°; relative humidity, green fruit, 90 to 95 percent; ripe fruit, somewhat reduced but not below about 85 percent)

The banana is one of the fruits that must be shipped to market in a green condition, as the ripened product is soft in texture and cannot well be handled without serious injury. The bunches of green bananas as they are received from the Tropics are usually ripened at a temperature of about 64° F., with a relative humidity of 90 to 95 percent or higher. If it is desired to hasten the ripening process, a higher temperature can be used (up to 70°) for the first 18 to 24 hours, but temperatures should then be reduced to about 66°. In any case relative humidity should be kept at 90 to 95 percent or higher until the fruit becomes thoroughly colored. After this it should be reduced slightly, but not below about 85 percent. Prolonged exposure to high temperatures will cause poor color and flavor and weak necks and will hasten decay.

The lowest temperature at which green bananas can safely be held in order to delay ripening is about 56°; below this they suffer an injury known as chilling—a form of peel injury to which both green and ripe bananas are susceptible, caused by low but not freezing temperatures. Ripe fruit is slightly more susceptible to chilling injury than green fruit. Fruit chilled in the green stage does not develop a bright-yellow color on ripening, but instead a smoky dull color. Fruit chilled after ripening will develop a dull-brown color when later exposed to higher temperatures and is very susceptible to handling marks, the slightest bruising causing discoloration.

The best holding temperature for ripe bananas is generally considered to be between 56° and 60°. At this temperature they will retain their good appearance and flavor and remain edible for a week or 10 days, although ordinarily they will not keep firm enough for shipment more than half that time (13).

BLACKBERRIES

Short storage only. See Raspberries.

CHERRIES

(Temperature, 31° to 32° F.; relative humidity, 80 to 85 percent)

Fresh cherries, either sweet or sour, are rarely held in cold storage for more than a few days. If held longer, they begin to lose flavor and the bright attractive appearance characteristic of the fresh fruit. The stems may also dry out noticeably, especially if the relative humidity is rather low. Sour cherries are often stored in a frozen state without sugar. They are usually precooled by being held at 32° F. for about 24 hours in the containers in which they arrive

from the orchard. They are then put in 50-gallon barrels and frozen at a temperature of about 0° and finally stored at 0° to 10°.

It is probable that the extreme limit for the successful commercial cold storage of fresh cherries at shipping point is about 10 days to 2 weeks. It is doubtful whether fresh cherries from California and the Northwest can be held satisfactorily in cold storage for more than about a week after arrival at eastern markets.

The sweating discussed on page 9 seems to be particularly troublesome on cherries because of the decay frequently associated with it after they are removed from a low temperature (38). Cherries cannot be shipped for any considerable distance without refrigeration, however, and hence are usually exposed for a few days to a week or more to whatever danger there may be from sweating after removal from the car. This means that most commercial lots of cherries should be placed under refrigeration or moved into consumption as quickly as possible after being unloaded.

COCONUTS

(Temperature, 32° to 35° F.; relative humidity, 80 to 85 percent)

Coconuts are best stored at 32° to 35° F. and can be held satisfactorily within that range for 1 to 2 months.

CRANBERRIES

(Temperature, 36° to 40° F.; relative humidity, 85 to 90 percent)

Cranberries are usually held in common or air-cooled storage, but are best stored at temperatures between 36° and 40° F. Storage for longer than about 4 months is not satisfactory because of the common occurrence of end rot, a fungus disease which can develop at low temperatures. Shrinkage of the berries as a result of water loss is also a limiting factor.

Cranberries for long-time storage are usually held unsorted in the picking crates as they go from the field. Thus handled, they seem to keep better than if sorted and cleaned previous to storage (59).

When stored at temperatures close to 32° F. cranberries are likely to develop a "low-temperature break-down" in which the berries are "rubbery" when pressed between the fingers, the flesh is permeated with red pigment from the skin, and some of the natural luster has disappeared. Such berries closely resemble those that have been frozen.

DATES

(Temperature, 32° F.; relative humidity, 65 to 75 percent; or 28° F. and no humidity control for cured grades)

Dates absorb moisture and odors readily from the air. The rate of absorption is much less at temperatures below 32° F. than at those above 32°. Deterioration caused by humidity above 75 percent is slow at storage temperatures below 28°. The dates of commerce are of three grades with respect to storage life—dry, cured, and noncured. The cured and noncured grades are perishable. A temperature as low as 0° has no deleterious effect upon dates but is actually beneficial to them.

Dates are of two different types, and fruits of each type are likely to be either dry, cured, or noncured. The "cane-sugar" type is usually firm, light-colored, and comparatively dry, whereas the "invert-sugar" type is usually softer, darker colored, and inclined to be slightly sticky or sirupy.

Deglet Noor, the most important variety grown in this country, is of the cane-sugar type. Dates of this variety, cured grade, keep well until March at 28° to 32° F. and for a year at 24° to 26° or lower, whereas the noncured grade requires 18° or lower for storage until March, and 0° to 10° for a year. In Deglet Noor dates that have become overripe or have been held under unfavorable storage conditions the cane-sugar is inverted and the dates become soft, sirupy, and darker in color. Such dates are commonly graded as "dark soft." If properly cured they can be stored at 28° to 32° until Christmas without becoming objectionably dark and sirupy, although a temperature of 0° to 10° will be needed if they are to be stored until March. If such dates are not cured a temperature of 0° to 10° is necessary for even short-time storage (41).

Halawy (Halawi), Khadrawy (Khadrawi), Zahidi, and Saidy dates are all of the invert-sugar type, and the cured grades can be kept until Christmas at 28° to 32° F. without forming sugar spots but require a temperature of 18° or lower if stored until March. Noncured grades of these varieties require 0° to 10° for even short storage. After Christmas it is well to shift all dates of invert-sugar type remaining in storage to "freezers" of 0° to 10° F. (2, 38).

DEWBERRIES

Short storage only. See Raspberries.

GRAPEFRUIT

(Relative humidity, 85 to 90 percent)

Storage rooms for grapefruit should have a relative humidity of 85 to 90 percent. Lower humidities are favorable to pitting, and higher ones may increase decay.

For short-time storage, grapefruit can be held satisfactorily at a temperature of 32° F. For longer periods the temperature to be used will depend on the character of the fruit and the troubles most likely to be encountered. For fruit grown in sections where stem-end rot is prevalent, this disease is likely to be the determining factor; it will generally be advisable to use a comparatively low temperature range (32° to 34°). On the other hand if the fruit is grown in regions where stem-end rot is not prevalent, the limiting factors are likely to be storage pitting and watery break-down, which develop most seriously at temperatures of 40° or lower. For such fruit a temperature of 45° to 55° is satisfactory. The more rapid development of undesirable high color and the increase in blue mold and green mold decay at the higher temperatures have not been found as objectionable as the pitting that results from storage at lower temperatures.

Sound fruit that is not overmature nor likely to suffer from stem-end rot can usually be held for 6 weeks without serious spoilage at the higher temperature ranges mentioned above, and this storage period can sometimes be doubled with satisfactory results. Weak or overmature fruit requires close watching from the time it is removed from the tree, regardless of storage conditions.

The percentage of stem-end rot in Florida and Texas grapefruit will be greatly reduced if the fruit is properly treated with borax or sodium metaborate, and pulled from the tree instead of being clipped. The disbuttoning that frequently results from the ethylene treatment is also effective in reducing loss from stem-end rot. As compared

with stem-end rot, blue mold and green mold rots are relatively less important in storage on Florida and Texas grapefruit. Stem-end rot is not known to occur on California fruit (5, 12, 42, 43, 55, 56, 57).

GRAPES

VINIFERA

(Temperature, 31° to 32° F.; relative humidity, 85 to 90 percent)

Large quantities of the European or vinifera grapes, grown principally in California, are stored every year. The most important of the varieties stored are Emperor and Ohanez (Almeria). Olivette de Vendemain, Malaga, Sultanina (Thompson Seedless), Cornichon, and Ribier are also occasionally stored. All of these have low freezing points, lower in fact than that of any other important fruit, largely because of their high sugar content. Although for most varieties there is no danger of freezing injury at temperatures as low as 28° F. (8), they are usually held at temperatures of 31° to 32°. At low air velocities a humidity of 85 percent prevents excessive wilting of stems and berries without favoring the formation of mold growth. At air velocities of 100 to 150 feet per minute a humidity of 90 percent is desirable (32).

California grapes for cold storage are packed in kegs or drums in sawdust or in various types of lidded lugs with or without sawdust. Good results are usually obtained, although if the fruit or the sawdust is damp at packing time or becomes so in storage there is danger of damage by mold. Mold may develop also if the grapes have been handled carelessly and if there are numerous cracked or loosened berries scattered through the pack. Varieties differ in keeping quality. The best storage varieties, packed in sawdust, can be held 2 to 4 months at 32° F. Emperor and Ohanez seem to keep better than any of the other storage varieties. Treating grapes with sulphur dioxide before placing them in storage has been found helpful in preventing decay. Sodium acid sulphite placed in the sawdust, in sawdust lugs or kegs, or in the pads at the top and bottom of display lugs releases sulphur dioxide over a long period and has given good control of decay without causing fruit injury, if not used in a too-strong concentration. The most effective, safe concentration of the sulphite is 5 to 10 grams per lug or keg (31).

Storage quality varies considerably from season to season and seems to be adversely affected by rain just before and during harvest. Grapes picked before rains usually keep better than those picked after rains.

AMERICAN

(Temperature, 31° to 32° F.; relative humidity, 80 to 85 percent)

The eastern or American varieties of grapes, the most important of which is Concord, are not adapted to long storage and most of them do not hold up well under storage conditions for more than 3 or 4 weeks. After that time they begin to deteriorate in flavor and may suffer heavily from decay if the temperature is not kept close to 32° F. The Catawba keeps better than most other eastern varieties and, if in good condition when stored, can be held for 3 to 4 months even in common storage in the districts where this variety is grown on a commercial scale.

Too low humidity is undesirable for grapes since it causes shriveling, especially of the stems. Stock intended for storage should be handled carefully to avoid cracking of the berries or loosening at the cap stem, because such injuries allow juice to exude and thus furnish favorable conditions for the beginning of decay.

Muscadine grapes are shipped only short distances if at all and are not known to be held in cold storage anywhere in commercial quantities (1, 22).

LEMONS

(Temperature, 55° to 58° F.; relative humidity, 85 to 90 percent)

From the standpoint of preventing decay (blue mold rot, green mold rot, and alternaria rot) in stored lemons, the lowest temperature that can be used without freezing the fruit would seem to be the most desirable. The difficulty is that at low temperatures certain non-parasitic troubles develop which are fully as serious as decay; among these are red blotch, pitting, and membranous stain. With proper humidity and at temperatures above 50° F. red blotch and pitting practically never occur and membranous stain is greatly reduced. The best results are usually obtained by storage at 55° to 58° in a humidity of 85 to 90 percent. Under such conditions lemons can be expected to hold up satisfactorily for periods of 1 month to as long as 4 months, depending on their maturity and condition when stored (6). Tree-ripened lemons, which are yellow when picked, do not keep well in storage.

If lemons have been handled carefully they will store better than if they have been injured by rough handling, because there will be fewer clipper cuts, scratches, and bruises and consequently less damage later by green mold rot and blue mold rot. The latter is able to penetrate the uninjured skin of lemons, but it is likely to cause more loss if the skin of the fruit is broken at numerous places. It can also grow from one fruit to another in the package and for this reason is frequently referred to as "blue contact rot." Air conditioning as now used in some of the lemon storage houses in California furnishes a means of preventing condensation of moisture on fruit and so decreases the danger of decay.

Lemons and other citrus fruits should not be stored in the same rooms with dairy products because of the readiness with which the latter absorb odors. Lemons in storage should be examined frequently to avoid loss from the sudden development of decay or other deterioration (6).

LIMES

(Temperature, 45° to 48° F.; relative humidity, 85 to 90 percent)

Preliminary investigations with Tahiti (Persian) limes indicate that fruit from a well-kept grove may be stored satisfactorily at a temperature of 45° to 48° F. for as long as 8 weeks, provided that the relative humidity is kept above 85 percent or the fruits wrapped individually in moisture-proof wraps. Prevention of desiccation is very important. For best quality, the Tahiti lime should be picked while still green but after the fruit has become "full" and smooth, having lost the "dimpled" appearance around the blossom end.

Key (Mexican or Dominican) limes can be stored satisfactorily at the temperatures recommended for Tahiti limes. The preferred color for this variety on the markets of the United States is yellow.

Temperatures above those recommended permit the development of stem-end rot, which is often a serious factor in the marketing of limes from Florida and the West Indies.

LOGAN BLACKBERRIES

Short storage only. See Raspberries.

OLIVES (FRESH)

(Temperature, 45° to 50° F.; relative humidity, 85 to 90 percent)

The best storage temperature for fresh olives (32) lies in the range between 45° and 50° F., and the safe storage period is 4 to 6 weeks. At lower temperatures the flesh of green fresh olives becomes brown, beginning around the seed and at the stem end. Ripe fresh olives develop more browning than green ones, showing severe discoloration even at 50°, if stored for more than about a month.

ORANGES

(Temperature, 32° to 34° F.; relative humidity, 85 to 90 percent)

Oranges are best stored at 32° F. and can usually be held at that temperature for 8 to 10 weeks without serious deterioration in appearance or flavor. However, some decay, chiefly blue mold rot or green mold rot, may occur during storage of 2 months or more under such conditions, and some fruit may begin to show pitting and brown stain of the rind. If stored for longer periods, decay increases, and the spotted fruit may gradually turn brown over all or most of the surface. Watery break-down may develop, as in grapefruit. Stem-end rot is likely to develop in Florida fruit if the storage temperature is higher than about 34°. Among California varieties, Washington Navel oranges are more subject to decay (blue mold and green mold rots) than Valencia oranges.

Careful handling is necessary at all times to avoid injury to the fruit and the decay, chiefly blue mold or green mold rot, that frequently follows injuries.

A free circulation of air around the boxes is desirable for oranges, as for other citrus fruit. A relative humidity of 85 to 90 percent is sufficient to hold the shriveling of packed oranges to a minimum and retards decay more than does a higher humidity.

Oranges should not be stored with eggs or butter or in places where it is possible for the orange odor to penetrate into egg or butter storage rooms. It is desirable that oranges in storage be examined regularly and often to avoid loss from sudden development of pitting or decay. After such examinations, a decision as to how long the fruit can safely be left in storage should take account of the fact that if pitting and decay are found they may increase rapidly after the fruit is removed to higher temperatures (7, 42, 43, 55, 57).

PEACHES

(Temperature, 31° to 32° F.; relative humidity, 80 to 85 percent)

Peaches are not adapted to cold storage. However, if they are sound and well-matured but not overripe, they can be held at 31° to 32° F. for 10 days to 4 weeks, depending on the variety, with little

or no bad effect on the flavor, texture, or appearance of the fruit. Storage for longer periods is usually harmful to all of these characters. The peaches lose their flavor and natural bright color and become dry and mealy or wet and mushy. In either case they show marked browning of the flesh, especially around the stone. The best storage varieties and their maximum storage period are: Late Crawford, 4 weeks; Elberta and J. H. Hale, 3 to 4 weeks. Belle, Champion, Hiley, and Carman are less desirable as storage varieties and cannot be expected to hold up well even under optimum conditions for more than 2 or 3 weeks (16, 17).

PEARS

(Temperature, Bartlett pears, 29° to 30° F.; fall and winter pears, 30° to 31°; relative humidity for all varieties, 85 to 90 percent)

BARTLETT PEARS

The successful storage of Bartlett pears (24, 25) depends not only on the temperature and humidity in the storage room but also on the condition of the fruit when stored. If the highest quality is to be obtained, Bartlett pears for storage should not be removed from the tree until the ground color begins to lighten and the lenticels have corked over. If picked before reaching that stage, they have a marked tendency to wilt, scald, and break down in storage. They also tend to break down in storage if picked when too ripe. The most desirable temperature for the storage of Bartlett pears is 30° to 31° F. The relative humidity should range from 85 to 90 percent. The maximum period for successful storage is 45 to 60 days.

FALL AND WINTER PEARS

For fall and winter varieties of pears (32, 33), such as Anjou, Bosc, Clairgeau, Comice, Easter Beurre, Hardy, Seckel, and Winter Nelis, the most desirable storage temperature is 30° to 31° F. A relative humidity of 85 to 90 percent is most commonly used. However, a relative humidity of 90 to 95 percent is maintained in some pear storage rooms in order to prevent shriveling. Such humidities are maintained in connection with air velocities of 100 to 200 feet per minute. The length of time for which it is safe to store these pears depends on the variety and when it is picked and also on whether the fruit is shipped directly to a consuming center and there stored or is stored at the shipping point for a time and later shipped to market. Information on these points is given in table 4. In using the table it should be remembered that wide differences in keeping quality are often found in pears from various producing sections of the country.

The commonest and most serious decay of fall and winter pears in storage is gray mold rot, caused by the fungus *Botrytis*, which is able to spread from decaying to sound healthy fruit. It is frequently called nest rot. Good control can usually be obtained by the use of paper wrappers impregnated with copper (9). If Bosc pears are held in cold storage beyond their season they do not ripen satisfactorily or they may not ripen at all.

TABLE 4.—*Length of time at various temperatures for safe storage of certain varieties of pears at shipping point and after shipment to market (33)*

Storage treatment and variety	Length of storage period	End of storage period
Stored immediately after harvest at 30° to 31° F.:		
Hardy.....	Months 2 to 3	September to November.
Comice.....	2 to 3	November to December.
Bosc.....	2 to 3	Do.
Claireau.....	6	February.
Winter Nelis.....	6 to 7	March to May.
Easter Beurre.....	5 to 7	Do.
Anjou.....	5 to 6	February to April.
Stored at 30° to 31° F. after 12-day transit period (not precooled):		
Bosc.....	2 to 3	November to December.
Claireau.....	2 to 6	October to February.
Winter Nelis.....	2 to 4	October to January.
Easter Beurre.....	4 to 6	January to March.
Stored at 30° to 31° F. after 12-day transit period (precooled):		
Hardy.....	2 to 3	October to November.
Comice.....	2 to 3	November to December.
Bosc.....	2 to 3	October to December.
Claireau.....	3 to 6	November to February.
Winter Nelis.....	6 to 7	March to May.
Easter Beurre.....	5 to 7	Do.
Picked in recommended range of 10 to 9 pounds: ¹ Hardy.....	(2)	
Picked in recommended range of 11.5 to 9 pounds: ¹ Comice.....	(2)	

¹ Degree of firmness as indicated by the pressure tester described by Magness and Taylor (27).

² Doubtful if fruit would arrive in firm enough condition to hazard commercial storage.

Kieffer pears, if they are sound, firm, and still green when stored and are held under the conditions recommended for other fall and winter pears, can be expected to keep satisfactorily for 2 or 3 months. If intended for storage, they should be handled with extreme care during the picking and packing process, because even slightly bruised or rubbed places are very likely to turn black and seriously damage the sales value of the fruit. Recent investigations (23) by the United States Department of Agriculture have proved that a ripening temperature of 60° to 65° F. is essential for the attainment of maximum quality in Kieffer pears for either dessert or canning purposes.

PINEAPPLES

(Temperature, ripe, 40° to 45° F.; mature green, 50° to 60° F.; relative humidity, 85 to 90 percent)

Pineapples are not adapted to long storage. Fully ripe fruits can be held satisfactorily at 40° to 45° F. for 2 to 4 weeks. Mature green fruits should not be held at temperatures below 50° and even at this temperature some of them will retain part of the green color in the skin and will fail to develop good flavor in the flesh after removal to room temperature. The maximum storage period for such fruit at 50° is 3 or 4 weeks. When held at 60°, mature green fruit ripens slowly, but after 2 or 3 weeks losses from decay, chiefly black rot, may be expected.

The relative humidity for pineapples in storage should range from about 85 to 90 percent (51, 52, 54).

PLUMS (INCLUDING PRUNES)

(Temperature, 31° to 32° F.; relative humidity, 80 to 85 percent)

Plums and prunes (fresh) are not stored extensively and are not adapted to long cold storage. Such varieties as Wild Goose and those of the damson type store better than the softer-fleshed plums

such as Santa Rosa, Beauty, Wickson, and Duarte; none of them can be expected to remain in good condition even at 32° F. for more than about 2 weeks. After that time they become too soft for commercial handling and lose somewhat in flavor.

The most important commercial shipping and storage variety is the Italian Prune. At a temperature of 32° F., 15 days is about the maximum cold-storage period for this fruit if a shipping period is necessary before the fruit goes on the market. After arrival at market prunes cannot safely be held in cold storage for more than about 3 weeks. If held longer there is danger that internal browning will develop, as well as abnormal odor and flavor.

QUINCES

(Temperature, 31° to 32° F.; relative humidity, 80 to 85 percent)

The behavior of quinces in storage is about the same as that of early winter varieties of apples such as Jonathan and Grimes Golden.

RASPBERRIES

(Temperature, 31° to 32° F.; relative humidity, 80 to 85 percent)

Fresh raspberries, blackberries, Logan blackberries, and dewberries are not adapted to storage and are usually not stored commercially. For short periods, 10 days to 2 weeks, they can be kept in fair condition by storage at 31° to 32° F. in a humidity of about 80 to 85 percent. Young dewberries can be stored satisfactorily for only a short time, rarely for as much as 10 days.

STRAWBERRIES

(Temperature, 31° to 32° F.; relative humidity, 80 to 85 percent)

Fresh strawberries are not stored commercially except for very short periods; 10 days is probably the maximum. Even for so short a time as this the temperature must be kept below 40° F. to prevent loss from decay caused by certain low-temperature fungi such as gray mold and *Phytophthora*, the fungus which causes leather rot; 31° to 32° is still better. After about 10 days, sometimes sooner, the fruit loses its fresh bright color, shrivels more or less, and deteriorates in flavor.

DRIED FRUITS

(Temperature, 32° to 50° F.; relative humidity, 70 to 75 percent)

Dried fruits, including prunes, raisins, apricots, peaches, and figs are held both in cold storage and in ordinary warehouse storage at temperatures ranging from 32° to 50° F. A relative humidity of 60 to 65 percent has been found most satisfactory for the storage of these commodities and is in fact about the degree of humidity which large operators often find has become established automatically in large rooms given over wholly to dried fruits. If stored in a warehouse, the packages of fruit are usually stacked close together to prevent excessive drying out. Dried fruits do not need the ventilation required by fresh, living fruits and vegetables. The storage room should not be in a basement because of the danger of too high humidity and the consequent development of mold; in fact, an upper floor is preferable, as such a location is usually drier. The storage

room should be kept dark and should be well screened to prevent the entrance of insects or rodents.

In cold storage, temperature and humidity conditions are more easily controlled, and vermin are usually held in check or kept out entirely by the low temperature. Dried fruits will usually keep for about a year in cold storage (at 32° F.), whereas in the warehouse or in common storage 4 to 6 months is often the extreme limit. After prolonged storage, even at low temperatures, dried apples darken, and prunes, figs, and raisins tend to "sugar," especially if their moisture content is high when they are first stored.

FROZEN FRUITS AND VEGETABLES

Frozen fruits in barrels should be held at about 0° to 10° F. if they are to be stored for several months. If the temperature of the fruit rises above 15° during the storage period there is danger of mold growth and spoilage.

For the freezing of fruits a temperature of 10° F. or lower is desirable for small containers and one of -5° to 0° for barrels. If freezing takes place too slowly the same undesirable conditions may develop that are encountered if the fruit is stored at too high a temperature after being frozen (11, 47).

For best results frozen fruits should be held in airtight containers.

The best temperature for freezing vegetables is from -10° to -5° F. For storage after freezing about 0° is satisfactory if ample provision is made for rapid cooling until the product reaches the freezing point.

NUTS

(Temperature, 32° to 50° F.; relative humidity, 75 to 80 percent)

Most of the commercial nut crop, including walnuts of all kinds, filberts, almonds, Brazil nuts, peanuts, and sometimes pecans, is usually held in ordinary warehouse storage through the winter following harvest. The portion of the crop (except pecans) that is to be kept through the following summer should be placed in cold storage early in March. Pecans become stale and rancid much sooner than most other kinds of nuts, and it is safer to put them in cold storage at 32° F. shortly after harvest. Brazil nuts can usually be kept satisfactorily in warehouse storage during the winter, but that portion to be held over summer should be stored at 32° before warm weather. Brazil nuts should be carefully inspected before being accepted for storage to see that they are well dried out or cured. Walnuts, filberts, and almonds usually need not be stored below 40° to 45°. Chestnuts are rarely held in any other way than in cold storage at 32° to 40°.

Shelled and unshelled peanuts can be held at common warehouse temperature during the winter, but during spring and summer shelled peanuts should be kept in cold storage both for protection against insects and to prevent development of rancidity. If cold storage is not available, peanuts should be stored in the shell and small lots shelled out as needed. Peanuts can usually be stored successfully in the shell in common storage. When shelled they darken and become rancid under these conditions, and therefore they should be shelled out only as needed. In common storage care should be taken to prevent infestation by insects. Fumigation is desirable for both shelled and unshelled peanuts if they are to be held in common storage during the summer.

Since shelled nuts do not keep as well as unshelled, it is usually the best practice to store nuts in the shell and crack them as needed unless the meats can be sealed in vacuum, which will permit them to be kept even longer than in the shell. Nut meats should be stored at 32° F.

The relative humidity of the storage room should be 65 to 75 percent. At higher humidities there is danger of mold growth, and at lower humidities there will be undue drying.

VEGETABLES

By R. C. WRIGHT, *physiologist*

The recommended temperature, relative humidity, and approximate length of storage period for the commercial storage of vegetables are given in table 5. Detailed descriptions of these requirements are given in the text following.

TABLE 5.—*Recommended temperature, relative humidity, and approximate length of storage period for the storage of various vegetables*

Commodity	Temperature	Relative humidity	Approximate length of storage period	Average freezing point ¹
	°F.	Percent		°F.
Asparagus.....	32	85 to 90	3 to 4 weeks.....	29.8

³ Rind.

⁴ See text.

ASPARAGUS

(Temperature, 32° F.; relative humidity, 85 to 90 percent)

Fresh asparagus is not usually stored except temporarily when the market is overstocked. Experiments have shown, however, that it can be kept successfully for 3 to 4 weeks at a temperature of 32° F. At this temperature, growth of the stalks, which takes place at higher temperatures, is practically nil. The original tenderness of fresh asparagus, which at ordinary storeroom temperatures is lost soon after cutting owing to the formation of woody tissue, is preserved at the lower temperature. Furthermore, the sugar content, to which asparagus owes some of its flavor and which after cutting rapidly diminishes at higher temperatures, remains practically the same as when the asparagus is cut, if it is put in storage immediately after cutting. Therefore, the sooner asparagus is placed in proper storage after harvesting the better will be its condition when used. The loss of water while in storage or transit is likely to be great if the stalks are not stood on wet moss or other moist absorbent material placed in the bottoms of the crates. In storage, asparagus bunches are sometimes set in water in shallow trays or pans. After a long haul to market, asparagus should not be expected to keep in storage for more than 3 to 6 days.

BEANS

(Temperature, 32° to 40° F.; relative humidity, 85 to 90 percent)

GREEN OR SNAP

Green beans are usually stored for only short periods. When held at 32° F. they may be expected to keep 3 or 4 weeks provided they are in good condition and are placed in storage promptly. The humidity should not be lower than 85 percent, to prevent wilting, and the hampers or other containers should be so stacked as to allow abundant air circulation. If the containers are packed close together the temperature may rise somewhat because of the heat given off by the commodity, and more or less rapid decay may be expected. If the beans are stored too long, the pods may become moldy or slimy. They should be free from surface moisture when stored and should be kept from contact with ice.

LIMA

Shelled lima beans are sometimes stored in quart baskets and, if fresh and sound when stored, can be expected to keep in good salable condition for about 15 days at 32° F. and about 4 days at 40°. If stored too long, the beans tend to fade to a light color and become sticky. Unshelled lima beans can be held satisfactorily for 3 to 4 weeks at 32° and 10 days at 40°.

BEETS

(Temperature, 32° F.; relative humidity, topped, 90 to 95 percent, bunched, 85 to 90 percent)

Late beets stored at 32° F. may be expected to keep 1 to 3 months under suitable storage conditions. Either cold storage or cellar storage is suitable, provided the humidity is kept sufficiently high to prevent wilting. Cellar storages often have a higher average temperature range than is recommended, and under these conditions the period of successful storage will be comparatively shorter. The temperature in such storage should not go above 45°. Beets are quite subject to

wilting because of the rapid loss of water and should be kept where the humidity is sufficiently high to prevent excessive evaporation.

Before going into storage, beets should be topped and well sorted to remove all diseased specimens and those showing mechanical injury, in order to prevent undue shrinkage because of storage decay. Beets may be stored in ventilated barrels or better in slat crates. Storage in large bulk should be avoided. Bunch beets may be stored at 32° for 10 days to 2 weeks if the leaves are free of surface moisture and the bunches are not packed so as to exclude air from the tops.

BROCCOLI (ITALIAN OR SPROUTING)

(Temperature, 32° F.; relative humidity, 85 to 90 percent)

Italian or sprouting broccoli does not keep well in storage and is usually held for only very short periods. The best storage temperature is 32° F. If in good condition and stored with sufficient ventilation between the packages, broccoli should keep satisfactorily for 10 days. Longer storage is undesirable because the leaves are likely to discolor and the buds may drop off (35).

CABBAGE

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

A large percentage of the late crop of cabbage is stored and sold during the winter and early spring, or until the new crop from the Southern States appears on the market. If stored under proper conditions, cabbage should keep for 3 to 4 months. The longest-keeping varieties belong to the Danish Ballhead class. Cabbage is most successfully held in common storage in the Northern States, where a fairly uniform inside temperature from 32° to 35° F. can be maintained. Many such storage houses are to be found, principally in New York, Pennsylvania, Michigan, and Wisconsin. Cabbage in quantity usually is not held in cold storage because its value does not justify the expense of handling.

Storehouses should be insulated sufficiently to prevent freezing, for although slight freezing does no harm, hard freezing is likely to cause considerable loss. More ventilating capacity than is required for most other vegetables should be provided to carry away the excessive moisture given off by the active respiration of this product and to obtain the maximum advantage of the cold night air during mild weather. Cabbage wilts quickly if held under too dry storage conditions; hence the humidity should be high enough to keep the leaves fresh and turgid. Bin storage is common, the bins usually being 4 to 5 feet wide and 10 to even 20 feet long and about 5 feet deep. They are best separated by slat partitions with 4-inch air spaces between. Tiers of bins may be built as high as it is convenient to elevate the cabbage. The use of slat shelves with the heads piled one or two layers deep is considered the best method, but is too expensive when large quantities are to be stored.

Cabbage should be handled carefully from the field to the storage. Before it is stored, the roots and all loose leaves should be trimmed away, and the damaged and misshapen heads should be culled out. On being removed from storage, the heads should be trimmed again to remove loose and damaged leaves.

CARROTS

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Carrots are stored in fairly large quantities during the winter. The marketing period for stored carrots extends to late winter or early spring when the new crop from the South appears on the market in competitive quantities. They are usually held in common storage in those sections where the storage temperature can ordinarily be held sufficiently low. Carrots are sometimes held in cold storage, although the prices obtained for them do not usually justify this kind of treatment.

It is generally considered that very light freezing causes practically no injury to carrots, but they should be protected from severe freezing and are best stored at a temperature of 32° F. They are subject to wilting or drying out if the humidity is not fairly high; for this reason they are more easily kept in a well-ventilated cellar or bank storage. The relative humidity should be maintained at 90 to 95 percent.

Before being placed in storage, carrots should be topped and all misshapen or injured specimens sorted out. The latter are especially objectionable because their presence in a storage lot favors the development of two serious diseases of stored carrots, namely, watery soft rot and bacterial soft rot. Carrots are best kept in slat crates or ventilated barrels, and allowance should be made for air circulation between the containers.

Bunch carrots may be stored for 10 days to 2 weeks, and the tops will still retain a fresh appearance if they are not crowded in storage and are free from surface moisture.

CAULIFLOWER

(Temperature, 32° F.; relative humidity, 85 to 90 percent)

Cauliflower is not usually kept in cold storage; however, an oversupply on the market can be stored for a short time to await more favorable conditions. Cauliflower can be held satisfactorily for 2 to 3 weeks at 32° F. Successful storage depends not only on preventing decay but also on retarding the maturing of the head or curd. Overmaturity is marked by a browning of the otherwise white curd and the development of a ricey appearance. The leaves also become yellowish and may drop off. Freezing causes a grayish-brown discoloration and softening of the curd, accompanied by a water-soaked condition.

CELERY

(Temperature, 31° to 32° F.; relative humidity, 90 to 95 percent)

Much of the late celery grown in the Northern States, notably New York and Michigan, is put into cold storage to supply the market up to the period in late winter when the competition of new celery from the South renders further holding unprofitable. Considerable celery from Florida is also put into cold storage toward the end of the shipping season in that State and held to supply the market during the summer, or until supplies of early, northern-grown stock appear on the market.

Celery is a rather perishable commodity and under unsuitable storage conditions may suffer severely from the disease known as watery soft rot. This disease originates in the field and is caused by a fungus that is able to develop to some extent even at temperatures of

34° to 36° F. For this reason celery intended for storage should be free from decay so far as can be determined by reasonably careful examination, and if held only in rooms where a uniformly low temperature can be maintained, it should keep for 2 to 4 months. It is best stored at a temperature of 31° or 32° F., with a humidity high enough to prevent wilting (90 to 95 percent), and with sufficient air circulation to keep the temperatures at the top and bottom of the room as nearly equal as possible. Considerable heat is given off by celery because of active respiration, and the air at the top of a storage room is likely to be 3° to 4° warmer than at the bottom unless special precautions are taken to avoid such a condition. Air circulation can be maintained around the crates by using 1- by 2- or 2- by 2-inch dunnage strips between the crates, which should be stacked so as not to touch at the sides.

Celery should not be piled more than four crates high in storage; otherwise there is danger of overheating even with stock that is in prime condition. If it is piled 5 to 8 crates high, as is sometimes done, the room should be watched carefully to see that overheating does not occur.

Some growth takes place in celery while in storage. The central stalks lengthen considerably, obtaining their food at the expense of the outer stalks and the roots. Blanching of the stalks also takes place in most varieties that are put into storage. Some celery is trimmed and washed as it comes from storage, but probably the larger part is shipped out in the original crates in which it was received (45).

CORN (GREEN)

(Temperature, 31° to 32° F.; relative humidity, 85 to 90 percent)

Green corn is seldom stored, although there are occasions during the southern shipping season when it may be desirable to put an excess supply of this commodity temporarily into cold storage; however, storage for more than a few days is liable to result in some impairment of flavor. The sugar content which so largely determines quality in this product and which rapidly decreases at ordinary temperatures is not greatly reduced. In order to keep this loss of sugar to a minimum and preserve the flavor, corn in the husks as it comes from the field for consumption in the fresh state should be cooled down about 32° F. as quickly as possible. This is best accomplished by submerging it in tanks of ice water for at least 30 minutes immediately after removal from the field.

Corn should not be handled in bulk because of its tendency to heat but should be put in baskets or crates which allow air circulation, in order to remove field heat and heat produced by respiration. This commodity as it usually arrives on the market should not be expected to keep satisfactorily in cold storage for more than 4 to 8 days.

CUCUMBERS

(Temperature, 45° to 50° F.; relative humidity, 80 to 85 percent)

Cucumbers are usually held in storage for only short periods and cannot be expected to keep satisfactorily for much over 10 to 14 days. The most favorable storage temperature range seems to be between 45° and 50° F., with a relative humidity of about 85 percent. When cucumbers are held for longer periods than recommended at 45° or

below, dark-colored watery areas appear, which are an indication of low-temperature injury. These areas soon become infected, and mold growth develops. If the cucumbers are held at 50° little or no breakdown develops within 4 or 5 weeks, but they tend to ripen, the color changing from green to yellow.

EGGPLANTS

(Temperature, 45° to 50° F.; relative humidity, 85 to 90 percent)

Eggplants cannot be expected to keep satisfactorily in storage for more than about 10 days.

ENDIVE OR ESCAROLE

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Endive or escarole is a leafy vegetable and therefore is not adapted to long storage as commercially handled. Even at 32° F., which is considered to be the best storage temperature, it cannot be expected to keep satisfactorily for more than 2 or 3 weeks. The storage requirements for endive are practically the same as for lettuce. Like lettuce it should keep somewhat longer than the period just mentioned if it is stored with cracked ice in or around the packages. The relative humidity in rooms where endive is held should be kept at 90 to 95 percent in order to prevent wilting.

A certain amount of desirable blanching usually occurs in endive that is held in storage.

GARLIC (DRY)

(Temperature, 32° F.; relative humidity, 70 to 75 percent)

Garlic is best stored under the temperature and humidity conditions required for onions. If in good condition and well cured when stored, this product should keep at 32° F. for 6 to 8 months. In central California, where considerable garlic is grown, it is frequently put in common storage, where it may be held for 3 to 4 months or sometimes longer if the building can be kept cool, dry, and well ventilated. Garlic is stored in loose mesh bags which are piled two layers deep in stacks separated by air spaces. It is essential that garlic be well cured in the field before going into storage.

HORSERADISH

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Horseradish should keep satisfactorily for 4 to 6 months if stored under the conditions recommended for carrots.

JERUSALEM-ARTICHOKE

(Temperature, 31° to 32° F.; relative humidity, 90 to 95 percent)

Jerusalem-artichokes, if held in storage at a temperature of from 31° to 32° F. in a relative humidity of 90 to 95 percent, may be expected to remain in good condition 2 to 5 months. At low humidities they shrivel badly and are more likely to decay than if kept in a moist atmosphere. They are sometimes stored in barrels or in paper-lined, airtight bags, in which they seem to keep longer, with less wilting and decay.

LEEKS (GREEN)

(Temperature, 32° F.; relative humidity, 85 to 90 percent)

Green leeks are crated and stored under conditions similar to those suitable for celery. If properly handled, they should keep satisfactorily for 1 to 3 months in storage.

LETTUCE

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Lettuce is sometimes put in cold storage when there is a surplus on the market, or in certain sections when the fall crop is threatened by approaching cold weather. If in good condition when stored, it can be expected to keep for 2 or 3 weeks. There is some evidence that it can be kept in better condition if ice is placed in the packages at the time of storage.

One of the most troublesome diseases of lettuce in transit and storage is tipburn of the type that develops in the interior of the head. This injury appears in the field, but in the later stages of the marketing process it is frequently followed by a slimy bacterial decay which may result in serious damage. Frequent inspection of stored lots is desirable.

MELONS

Cold storage is used very little for most kinds of melons. When it is used, the storing is generally done at the terminal markets to avoid temporary adverse market conditions. The results of extensive studies made by the U. S. Department of Agriculture offer little encouragement for the successful storage of either cantaloup or Honey Dew melons for more than comparatively short periods after arrival at the market.

WATERMELONS

(Temperature, 36° to 40° F.; humidity, 75 to 85 percent)

The ordinary commercial varieties of watermelons cannot usually be expected to keep in storage for more than 2 or 3 weeks. Experimental lots have been held at temperatures of 32° F. and did not develop decay as rapidly as at the recommended temperatures, but there was a tendency for the melons to become pitted or dented and to take on an objectionable flavor after 1 week.

CANTALOUPS

(Temperature, 32° to 34° F.; relative humidity, 75 to 78 percent)

The common commercial varieties of cantaloups can be expected to keep 1 week in cold storage at the recommended temperatures after arrival on the market and, under favorable conditions, for a few days longer but not as long as 2 weeks. The riper the melons are on arrival, the shorter the storage period should be. When they are held too long in storage, decay develops so rapidly on removal that they soon become practically worthless.

HONEY DEW AND HONEY BALL MELONS

(Temperature, 36° to 38° F.; humidity, 75 to 85 percent)

Honey Dew and Honey Ball melons can usually be kept a little longer in storage than cantaloups. At 36° to 38° F. or slightly lower they can be expected to keep for 2 weeks and still reach the consumer

in good condition. If held for a longer time at temperatures below 36°, low-temperature break-down marked by a watery discoloration of the rind, followed by fungus decay will probably result; at 36° to 38° decay may occur which will seriously discolor the rind. All blemishes show more plainly on these melons because of their light-colored, smooth surfaces.

CASABA AND PERSIAN MELONS

(Temperature, 36° to 40° F.; humidity, 75 to 85 percent)

Casaba and Persian melons are relatively good keepers. They will remain in good condition in storage for at least 4 weeks and have been reported to keep as long as 6 weeks.

MUSHROOMS (CULTIVATED)

(Temperature, 32° to 35° F.; relative humidity, 80 to 85 percent)

Mushrooms do not keep well in storage and are therefore stored only temporarily for periods of 2 to 3 days. They are easily injured by freezing.

ONIONS AND ONION SETS

(Temperature, 32° F.; relative humidity, 70 to 75 percent)

Onions are held in either common or cold storage. In the northern onion-growing States, strongly flavored varieties, mostly of the globe type, are generally held in common or dry storage. The principal northern onion-producing States have a sufficiently low average winter temperature so that onions can be successfully held in common storage there during the winter months. About one-fourth of the onion crop of these States, however, is put into cold storage for consumption late in the spring. About the first of March is considered as late as onions should be held in common storage, because after this time there is danger of sprouting. The mild, or Bermuda types, such as those produced in Washington, southern California, Texas, and other States, where the climate is not suitable for common storage, are usually consumed shortly after being harvested. These onions can be, and limited quantities are, held in cold storage, but usually for much shorter periods than the globe varieties because of their poorer keeping qualities. The Spanish or Valencia type of onions grown in this country are often stored and, if well matured, are considered capable of storage for practically as long as the globe type.

A comparatively low relative humidity (70 to 75 percent) is very desirable for the successful storage of onions. At higher humidities, in which many other vegetables keep best in storage, onions are disposed to root growth and decay. The commonest form of the latter is gray mold rot occurring at the top of the bulb, whence its name "neck rot" (48). The fungus causing it can develop to some extent even at 32° F.; hence onions intended for storage should be carefully sorted over to remove all diseased bulbs. A uniform temperature of 32° is found to be sufficiently low to keep onions dormant and reasonably free from decay provided they are in good sound condition and well cured when stored.

Onions are not perceptibly injured by slight freezing if allowed to thaw out slowly and without rough handling. In cold storage they are usually held in bags of 50 or 100 pounds each, which are best piled in pairs laid crosswise in stacks five or six sacks high. The stacks should be set a few inches off the floor on 2- by 4-inch strips and the

individual stacks separated by a few inches of space to allow for air circulation. When kept in common storage, onions are best stored in slat field crates holding about 1 bushel, rather than in bags. Before being placed in storage onions should be well dried or cured in the field for a period of 4 to 6 weeks and all decayed specimens or those showing thick or "bottle" necks should be sorted out.

Onion sets are usually held in common storage. They require nearly the same conditions as large onions and are best stored in shallow slat-bottom crates or trays not over 4 inches deep and about 5 by 5 feet in some districts or 2 by 3 feet in others. The corner posts of the crates should project about an inch above the side pieces in order to prevent the crates from resting tightly on each other when stacked and to allow air circulation between them. Because of their size, onion sets tend to pack closely in the crates; hence it is essential to allow as much air circulation as possible and to maintain a comparatively low humidity.

PARSNIPS

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Parsnips have nearly the same storage requirements as carrots and should keep for 2 to 4 months. They are not injured by slight freezing while in storage but should be protected from hard freezing and should be very carefully handled while in a frozen condition. Parsnips dry out readily in storage; hence it is essential that the humidity of the storage place be kept relatively high. Parsnips are sometimes stored in sand or clean soil to prevent wilting, but they will keep in good condition when held in barrels or crates if the proper humidity is maintained.

PEAS (GREEN)

(Temperature, 32° F.; relative humidity, 85 to 90 percent)

Much the same storage conditions are required for green peas as for beans. Shortly after being picked, green peas tend to lose part of their sugar content on which much of their flavor depends. They cannot be expected to keep in salable condition for more than 1 to 3 weeks unless packed in crushed ice, in which condition the storage period may be extended perhaps a week. Peas keep better unshelled than shelled.

PEPPERS

CHILI PEPPERS (DRY)

(Temperature, see text; relative humidity, 70 to 75 percent)

Chili peppers are usually picked when ripe and then dried and allowed to equalize in moisture content in covered piles. Water is usually added to the peppers after drying, and as a result they become less brittle. They are then packed tightly by tamping into sacks holding 200 to 300 pounds and stored in warehouses for a period often lasting for 6 to 9 months.

The temperature of the warehouses depends to some extent on their construction and the way in which they are managed but chiefly on the outside temperature. In southern California, where a large part of the commercial crop of Chili peppers is produced, the outside temperature ranges from 50° to 80° F. during the usual storage period.

The moisture content of Chili peppers when stored is generally low enough (10 to 15 percent) to prevent mold growth; the chief storage trouble is insect infestation. Some manufacturers of Chili-pepper products hold part of their supply of the raw material in cold storage if this seems necessary, but they prefer to grind the peppers as soon as possible and store them in the manufactured form in air-tight containers.

SWEET PEPPERS

(Temperature, 32° F.; humidity, 85 to 90 percent)

Sweet or bullnose peppers, if in good condition, may readily be kept fresh in storage for a month to 6 weeks at a temperature of 32° F. A humidity of 85 to 90 percent is desirable to prevent shrinkage (20).

POTATOES

(Temperature, 36° to 50° F.; humidity, 85 to 90 percent)

Potatoes are stored either in cold or common storage, but the greater part of the crop that is stored is held in common storage (44). Like most other vegetables that can be held for relatively long periods in common storage, only in the northern tier of States, where a sufficiently cold winter climate prevails, can potatoes be successfully kept through the fall and winter months. In either cold or common storage a temperature of 40° F. is as low as table or seed stock need be kept during the first few months after harvest. At temperatures below this, there is a tendency for potatoes to become undesirably sweet. However, if sweetening occurs, a few days' exposure to ordinary living-room temperature will partly restore the natural flavor. At 40° potatoes will remain dormant 3 to 5 months after harvest, depending on the variety. If it is desired to keep them longer than this, as is often the case with seed stock, the temperature may be lowered to 36° or 38° F., where they should remain dormant indefinitely.

Recent investigations (30, 60) have indicated that potatoes stored at 50° to 60° F. have better texture, color, and flavor when cooked or made into chips than the same stock stored at lower temperatures, although the higher temperatures are not suitable for long-time storage. When potatoes are stored at these higher temperatures, sprouting will more quickly become apparent. A limited amount of sprouting does not injure potatoes for food purposes, but it makes the stock difficult to market because usually only dormant potatoes are wanted. After sprouting has started it can be checked by lowering the storage temperature.

The relative humidity of a potato-storage house should be 85 to 90 percent, to prevent undue shrinkage through loss of water. In cold storage potatoes are generally kept in sacks holding from 100 to 150 pounds net; in common storage they are usually placed in bins holding from 150 to as much as 1,000 bushels or more. Farther north, as in Maine or northern New York, where the average temperature is sufficiently low, the large-bin storage is used with success, but in the States in the latitude of Pennsylvania it is doubtful whether potatoes should be stored in such large units. Potatoes are readily injured by even slight freezing, which takes place at about 29° F. or slightly below; hence common-storage buildings should be sufficiently insulated to prevent freezing. Insulation will also prevent the condensation of

moisture on the walls and ceilings, and the consequent undesirable wetting of stored stock, which favors the development of decay (39). Sufficient ventilation should be provided in common storage to take advantage of the cool night air in mild weather which will aid in preventing excess moisture and maintain a lower average temperature. Ventilators should never be opened, however, when the outside temperature is higher than that inside the storage house.

Potatoes intended for storage should be handled carefully to avoid bruises and cuts; otherwise they are likely to be damaged by various forms of decay before the end of the storage period.

PUMPKINS

(Temperature, 50° to 55° F.; relative humidity, 70 to 75 percent)

In general most varieties of pumpkins will not keep in storage as long as the usual storage varieties of squash. Such varieties as Connecticut Field and Cushaw are relatively poor keepers and cannot be expected to hold in good condition more than 2 or 3 months. Varieties like Large Cheese and Table Queen will keep 3 to 6 months.

Hard-shell squashes, such as the Hubbards, can be successfully stored for 6 months or longer.

All stock should be well matured, carefully handled, and free from injury or decay when put in storage. The best storage temperature appears to be from 50° to 55° F. with a relatively low humidity of about 70 to 75 percent. Investigations have shown that a preliminary curing at 80° to 85° F. for about 2 weeks is of benefit in ripening immature specimens and in healing mechanical injuries incident to harvesting.

RADISHES (WINTER)

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Winter radishes require the same storage conditions as carrots and should keep in good condition for 2 to 4 months.

RHUBARB

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Rhubarb stalks, if fresh and in good condition, may be stored for 2 to 3 weeks. The bunches should be packed in crates which are stacked to allow ample air circulation on all sides, otherwise there is danger of heating and also mold growth.

RUTABAGAS

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Rutabagas require the same storage conditions as carrots and should keep satisfactorily under such conditions for 2 to 4 months.

SALSIFY

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Salsify has the same storage requirements as carrots. The roots are not injured by slight freezing but should be carefully handled while frozen. Under the conditions specified, they should keep for 2 to 4 months.

SPINACH

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Spinach is usually stored for only short periods. It should keep fairly well for a week or two after being cut. If crushed ice is used in the packages, this period can be extended somewhat.

SQUASHES

See Pumpkins.

SWEETPOTATOES

(Temperature, 50° to 55° F.; relative humidity, 80 to 90 percent)

The requirements for the successful storage of sweetpotatoes differ from those recommended for most other vegetable crops. When freshly dug sweetpotatoes are to be stored for any length of time they should be given a preliminary curing treatment to permit the healing of all wounds or abrasions incident to harvesting and handling, in order to prevent the entrance of decay organisms.

The curing and storing are done in the same house so that the potatoes do not have to be moved after the curing treatment. When commercial lots are handled, the storage house is generally of special construction with sufficient insulation to maintain a uniform temperature and some means of ventilation that will insure the desired humidity. Provision should be made for heating the building during the curing process and for holding the proper storage temperature afterward. The curing process ordinarily takes from 10 to 14 days, during which the house is kept at a temperature of 80° to 85° F., with a relative humidity of 85 to 90 percent. After the curing period the storage temperature is allowed to drop to from 50° to 55°, with a humidity of 80 to 85 percent. Short periods of a few hours at temperatures somewhat lower than 50° need not cause alarm, but prolonged periods of low temperature should be avoided because of the danger from certain types of decay which are more likely to develop at temperatures below the range given (19, 46).

Only well-matured stock that is practically free from mechanical injury or decay should be used for storage. Sweetpotatoes are usually stored in slat crates of about a bushel capacity or in bushel baskets. Shallow bins are sometimes used. The roots should be handled as little as possible during storage.

TOMATOES

(Temperature, ripe, 40° to 50° F.; mature green, 55° to 70°; relative humidity, 85 to 90 percent)

Ripe tomatoes are held in storage only temporarily and should not be stored at temperatures lower than 40° F. At 40° to 50°, if not already soft ripe, they will keep in good condition for a week to 10 days; at temperatures lower than this they sometimes show a tendency to break down.

Green tomatoes are best kept at a temperature not lower than 55°. At this temperature ripening progresses slowly but satisfactorily, and mature green tomatoes can be kept for 1 to 6 weeks before becoming overripe. At temperatures below 55° green tomatoes do not ripen well and, if kept there more than 5 to 8 days and then moved to a warmer place, usually do not ripen satisfactorily. Exposures up to 5 to 8 days to a temperature of 40° or even somewhat less do not usually prevent mature green tomatoes from ripening satisfactorily, when later removed to a favorable temperature. If fairly rapid ripening is desired, temperatures from 60° to 70° should be used. At 70° or above, ripening is accelerated, but so also is the development of decay, which it will be found difficult to control. The relative humidity of tomato storage or ripening rooms should be from 80 to 85 percent (61).

TURNIPS

(Temperature, 32° F.; relative humidity, 90 to 95 percent)

Turnips require the same storage conditions as carrots. They can be expected to keep for 2 to 4 months.

FROZEN VEGETABLES

For treatment of frozen vegetables see p. 22.

CUT FLOWERS, FLORISTS' GREENS, RHIZOMES, TUBERS, CORMS, AND BULBS

By T. M. WHITEMAN, *assistant horticulturist*

The recommended temperature, relative humidity, and approximate length of storage period for the commercial storage of cut flowers, florists' greens, rhizomes, tubers, corms, and bulbs are given in table 6. Detailed descriptions of these requirements are given in the text following.

TABLE 6.—*Recommended temperature and approximate length of storage period for cut flowers, florists' greens, rhizomes, tubers, corms, and bulbs*¹

Commodity	Temperature (°F.)	Approximate length of storage period	Commodity	Temperature (°F.)	Approximate length of storage period
Cut flowers:²			Cut flowers—Contd.		
Babysbreath.....	40	3 to 4 days.	Primrose.....	35-40	3 to 4 days.
Bouvardia.....	40	7 to 10 days.	Rose.....	35-40	1 week.
Butterflybush.....	40	3 to 4 days.	Snapdragon.....	40	3 to 4 days.
Calendula.....	40	3 to 6 days.	Snowdrop.....	32-36	2 weeks.
Calla.....	40	10 days.	Squill.....	32-36	Do.
Candytuft.....	40	3 to 6 days.	Statice.....	35-40	3 to 6 weeks.
Carnation.....	40	1 week.	Stevia.....	40	3 to 4 days.
China-aster.....	40	7 to 10 days.	Stock, common.....	40	3 to 6 days.
Chrysanthemum.....	35	2 weeks.	Strawflower.....	35-40	1 month.
Clarkia.....	40	3 to 6 days.	Sweet pea.....	40	3 to 4 days.
Columbine.....	40	3 to 4 days.	Tulip.....	32-36	2 weeks.
Cornflower.....	40	3 to 6 days.	Violet.....	32-38	3 to 6 days.
Crocus.....	32-36	2 weeks.	Florists' greens:²		
Dahlia.....	40	7 to 10 days.	Ferns:		
Daisy, English.....	40	3 to 6 days.	C o m m o n	32-45	2 weeks to 4 months.
Delphinium:			wood.....		
Hardy lark-	40	Do.	Dagger.....	40-45	Do.

Freesia.....	32-36	2 weeks.	Rhizomes, tubers,		
Gaillardia.....	40	3 to 6 days.	corms, and bulbs:³		
Gardenia.....	45-50	1 week.	Begonia, tuber.....	45	4 to 6 months.
Gladiolus.....	35	2 weeks.	Caladium.....	45	Do.
Heath.....	40	7 to 10 days.	Calla.....	35	6 to 8 months.
Hyacinth.....	32-36	1 week.	Canna.....	45-50	6 to 7 months.
Iris.....	40	7 to 10 days.	Crocus.....	55-60	4 to 6 months.
Laceflower.....	40	3 to 6 days.	Dahlia.....	45-50	6 to 7 months.
Lily:			Freesia.....	55-60	4 to 6 months.
Easter.....	35	1 month.	Gladiolus.....	40-50	7 to 8 months.
Goldband.....	35	Do.	Hyacinth.....	55-60	4 to 6 months.
Speciosum.....	35	Do.	Lily-of-the-valley.....	25-28	12 to 14 months.
Lily-of-the-valley.....	40	1 week.	Lily:		
Lupine.....	40	3 to 6 days.	Easter.....	35	6 to 8 months.
Narcissus.....	32-36	2 weeks.	Regal.....	35	Do.
Orchid, cattleya.....	45-50	1 week.	Narcissus.....	55-60	4 to 6 months.
Peony:			Snowdrop.....	55-60	Do.
Tight buds.....	35	3 to 4 weeks.	Squill.....	55-60	Do.
Loose buds.....	35	10 to 14 days.	Taro.....	45	Do.
Phlox.....	40	3 to 4 days.	Tuberose.....	40-45	6 to 8 months.
Poinsettia.....	50	Do.	Tulip.....	50-55	4 to 6 months.

¹ See footnote 1, table 3. The average freezing points which have been determined for certain cut flowers are as follows: Gardenia 28.3° F.; sweet violet 28.5°; Easter lily 27.5°; orchid (cattleya) 30.1°; peony 29.1°; rose 30.0°; chrysanthemum 28.4°; gladiolus 28.7°; ranunculus 28.6°; tulip 28.0°; narcissus (daffodil) 30.1°; for bulbs, corms, etc.: hyacinth 28.7°; Regal lily 27.1°; tulip 25.4°; narcissus (daffodil) 26.1°; narcissus (Paper White) 28.9°; dahlia 28.3°; gladiolus 26.8°; lily (calla) 27.5°; for foliage: Holly 26.5°; sweet violet 27.4°; and dagger fern 23.6°.

² Approximately 80 percent relative humidity.

³ Approximately 75 percent relative humidity.

CUT FLOWERS

Most cut flowers are benefited by a freshening period of a few hours in water at about 50° F. immediately after being cut. Cold-storage rooms for the holding of cut flowers for short periods are operated mainly by wholesale florists in the large cities. The temperatures given in this section are recommended to insure a reasonably long life for flowers after their removal from storage.

Cut flowers in storage should be kept with the stems in water. They should not be crowded in the containers because of the danger of mechanical injury and the decay that may result because of lack of ventilation. In most cases care should be taken not to spill water on the blooms since these usually discolor quite readily.

Chrysanthemums (*Chrysanthemum hortorum*) and gladioluses (*Gladiolus* spp.) may be stored at 35° F. for 2 weeks and usually remain very salable. Longer storage is possible, though frequently not practicable. These flowers are usually tied in bunches of 12 and 25, respectively, but are not wrapped when placed in storage. Pompons, however, are sold in bunches of various sizes.

As a rule the proper cutting stage for the large-flowering types of chrysanthemums is just after the green color in the center of the flower has disappeared. No general rule can be given for pompons, since several varieties, especially some of those in the anemone group, need more development on the plant than the single varieties.

Gladioluses should be cut when three or four of the lower buds show color and are partly opened. For distant shipments before storage the flowers should show color but should be in the tight-bud stage.

Easter lily (*Lilium longiflorum*), common peony (*Paeonia officinalis*), Chinese peony (*P. albiflora*), Speciosum lily (*L. speciosum*), Regal lily (*L. regale*), and goldband lily (*L. auratum*) can be held at 35° F. for comparatively long periods, although 30 days is usually the maximum storage period. The lilies in this group should be cut for storage when the corolla is about one-half opened, or just before the tips begin to reflex. Lilies forced at relatively high temperatures should be kept at a temperature of about 50° for a preliminary period of about 24 hours before being put at 35°. Peonies showing color in the tight-bud stage may be stored at 35° for a month or more, but they seldom give satisfaction for decorative purposes without special handling; in the loose-bud stage they may be held satisfactorily for 10 days.

The cut blooms of callas (*Zantedeschia aethiopica* and *Z. elliottiana*) may be stored when fresh for as long as 10 days at 40° F., and will be in good condition upon removal. Calla blooms should be gathered just before the spathe shows signs of curling downward. Callas that have been subjected to hard forcing should be held for about 24 hours at a temperature of 50° previous to storage at 40°. When the blooms are gathered they should be pulled, not cut, otherwise the stems will split at the cut ends and curl after a few days in storage. The pulling method separates the stem from the rhizome, leaving no useless appendage. Although the blooms are sometimes removed from the plant by cutting, the stub left on the plant will probably rot and thus may serve as a place of entrance for disease organisms. Pulling, however, is much easier with potted callas than with those planted in beds or benches. Callas intended for storage should be tied at the bottom

and also loosely tied below the blooms. They are usually put up in lots of one dozen.

Lupine (*Lupinus*), clarkia (*Clarkia* sp.), common stocks (*Matthiola incana*), candytuft (*Iberis*), delphinium, hardy or perennial larkspur (*D. formosum* and hybrids), cornflower (*Centaurea cyanus*), feverfew (*Chrysanthemum parthenium*), common snapdragon (*Antirrhinum majus*), blue laceflower (*Trachymene caerulea*), English daisy (*Bellis perennis*), calendula or pot-marigold (*Calendula officinalis*), and common perennial gaillardia (*Gaillardia aristata*) should not be held at temperatures lower than 40° F., and cannot be stored with good results for more than a 3- to 6-day period. Violets are usually made up in bunches of 100, supported underneath by a few galax leaves and wrapped with a light waxed paper and should be stored at 32° to 36°.

Columbine (*Aquilegia* sp.), stevia (*Piqueria trinervia*), babys-breath (*Gypsophila paniculata*), annual larkspur, baby primrose (*Primula forbesi*), sweet pea (*Lathyrus odoratus*), true forget-me-not (*Myosotis scorpioides*), and orange-eye butterflybush (*Buddleia davidi*), all have flowers whose petals shed quickly, almost regardless of temperature. They cannot be held much lower than 40° F., nor for longer than 3 to 4 days without impairing the keeping quality after removal. Forced *Buddleia* is sold by the dozen. The others mentioned are bunched in lots of 25. It is not customary to wrap any of these for storage.

Orchids and gardenias (*Gardenia florida*, *G. veitchi*, and *G. fortunei*) are not customarily stored for long periods. However, they may be kept in storage in good condition for about a week at a temperature of 45° to 50° F. They keep best when cut just after they have reached a salable condition.

Carnations (*Dianthus caryophyllus*) are preferably held at a temperature of 40° F., although 35° may be used for comparatively long periods. The best cutting stage is immediately after the center of the flower has developed sufficiently to be considered salable. They are customarily put up in lots of 25 by the grower and should be tied securely at the bottom and more loosely just below the blooms.

Roses for nearby markets should be cut in the loose-bud stage; if they are to be shipped to distant markets they should be in the tight-bud stage but showing color. In the loose-bud stage they may be held at 35° to 40° F. for 1 week; stored at lower temperatures the subsequent keeping qualities are often impaired. They are usually tied by the grower in bunches of 25, and the buds and upper parts of the stems are wrapped tightly in waxed parchment paper to prevent bruising and possible opening of the petals.

Dahlias (*Dahlia* sp.), China-asters (*Callistephus chinensis*), sweet bouvardia (*Bouvardia humboldti*), heath (*Erica* sp.), and the various forced irises may be held for 7 to 10 days at 40° F. They usually are handled in lots of 1 dozen, tied, but not wrapped.

Statice, including bigleaf and notchleaf sea-lavender (*Limonium latifolium* and *L. sinuatum*, respectively), and strawflower (*Helichrysum bracteatum*) may be kept at 35° to 40° F. for 3 to 6 weeks. They may be dried and will retain their original color and shape; strawflowers are usually dried instead of being stored to retain their freshness.

Common foxglove and common white foxglove (*Digitalis purpurea* and *D. purpurea alba*, respectively) and garden phlox (*Phlox pani-*

culata) are not usually satisfactory for storage but may be held for 3 or 4 days at 40° F.

Cut poinsettias (*Poinsettia pulcherrima*) sold during the Christmas season usually need not be stored for the few days between their arrival at the wholesale house and the day of sale. If holding is necessary, storage at about 50° F. is recommended. Any change of environment, such as improper storage, will increase the apparently inherent tendency of poinsettias to shed their foliage. They should be cut when showing sufficient color to be salable. Searing the cut ends with boiling water is a practice usually followed to prevent undue loss of sap previous to or during storage.

Cut lilies-of-the-valley (*Convallaria majalis*) are kept satisfactorily at 40° F. and may be held for 1 week at this temperature; if they are kept longer the lower bells often become watery in appearance (53). The proper cutting stage is just after the terminal bell has lost its deep-green color. It should be of a yellow-green appearance, the lower 3 or 4 bells at this time being well opened. They are usually tied with foliage in bunches of 25 and are better wrapped loosely in heavy waxed paper, leaving the tops and bottoms of the bunches open.

Hyacinths, tulips, narcissus, freesias, squills, snowdrops, and crocuses can usually be held satisfactorily for 2 weeks at 32° to 36° F.

Spikes, such as snapdragon, should be cut just after the lower 5 or 6 flowers have fully opened; umbels, such as blue laceflower, should be cut just after they develop to a salable condition; flowers formed in heads usually should be cut after the outermost petals are fully developed and just before stamens appear in the center of typically single heads or after the center has become closed with petals in double sorts; corymbs, such as candytuft, are usually best when cut after three-fourths of the lower flowers are opened; those described as thyrses or corymbose cymes, such as the lilac, should be cut when about two-thirds of the determinate branches are developed; cymose clusters, such as babysbreath, should be cut after a few of the terminal flowers have developed.

FLORISTS' GREENS

Fern asparagus (*Asparagus plumosus*) and smilax asparagus (*A. asparagoides*) are usually shipped in crates. The turn-over of these greens is rapid and shipments are arranged so that storage for longer than 3 or 4 days is usually unnecessary, but they may be kept in the case for 7 to 10 days at 40° to 45° F. The sprays of *A. plumosus* are tied in bunches of various sizes. Smilax is packed in the crates in various lengths or "strings." The commercial popularity of *A. sprengeri* has declined to a point where it is produced and used chiefly by small retail growers.

Drooping leucothoe (*Leucothoe catesbaei*) and mountain-laurel (*Kalmia latifolia*) sprays may be held in good condition at 32° to 40° F. for 3 to 6 weeks. They are usually tied in bunches and kept standing in containers of water.

Galax (*Galax aphylla*), groundpine (*Lycopodium* sp.), huckleberry, dagger ferns, common woodferns, and various species including *Dryopteris intermedia*, packed in crates, may be held at 32° to 45° F., depending on the length of time it is desired to keep them. At 32° they may be expected to keep 1 to 3 months, whereas at 45° they may be kept for but 2 to 3 weeks in good condition. They are not put in

water, but if stored loose they are kept moist by occasional sprinklings. If held in wooden cases or packed in such a way as to prevent excessive drying out by direct air currents, no sprinkling is necessary. Galax is usually tied in bunches of 25; the ferns are tied in lots of 50, but both are customarily sold by the hundred. Those who make a business of gathering the greens in this group sometimes store them in coldframes, covering them with about 6 inches of some material such as sphagnum moss or leaves, and shading or using sash as the weather demands. Handled in this way, shipments can be made at any time. Others who might be termed "brokers" have many employees gathering galax and ferns and store their entire holdings in cold-storage warehouses; this is the method commonly employed for storage, and it usually gives satisfaction.

Holly sprays or wreaths can usually be held satisfactorily for approximately 1 month at a temperature of 32° F. and a relative humidity of about 80 percent.

RHIZOMES, TUBERS, AND CORMS

Lily-of-the-valley pips or crowns may be held in cold-storage warehouses at a temperature range of 25° to 28° F. (53) for 15 to 17 months, although after about 12 months increasing deterioration in quality becomes noticeable. The pips are tied in bundles of 25 with string or willow ties and are packed in wooden cases of various sizes containing from 250 to 2,500 pips.

Taro (*Colocasia esculenta*), spotted caladium (*C. neoguineensis*), and tuber begonias (*Begonia tubehybrida*) may be held at 45° F. and a humidity of 75 to 80 percent for several months. They should be packed in dry sawdust or peat.

Cannas (*Canna indica*), dahlias (*Dahlia* sp.), and peonies (*Paeonia* sp.) may be stored at 45° to 50° F. over a period of 6 to 7 months with a humidity of 70 to 80 percent. They are usually packed in dry soil or sawdust.

Gladiolus sp. (mostly hybrids) stored at 40° to 50° F. and at a humidity of 70 to 75 percent will keep in good condition for the normal storage period of 7 to 8 months. They should be stored dry in shallow trays with ample ventilation, but only after a curing period of 3 to 6 weeks in an open or well-ventilated shed.

Common and golden callas (*Zantedeschia aethiopica* and *Z. elliotiana*) stored at 35° F. and at a humidity of 70 to 75 percent in dry soil or peat will keep for many months if it is necessary to store them. The normal rest period in the forcing cycle is during May, June, and July. Unless water is withheld during this period complete dormancy will not exist. Therefore, storage in a dry condition is essential, with sufficient humidity to prevent undue shriveling.

BULBS

Most varieties of *Narcissus* sp., hyacinths (*Hyacinthus orientalis*), freesias (*Freesia refracta alba*), tulips (*Tulipa* sp.), squills (*Scilla* sp.), snowdrops (*Galanthus nivalis*), *Crocus* sp., and similar bulbs may be held in common storage for several months. However, many of them are still imported in large numbers, and these are usually not stored since better results are obtained by planting them as soon as they arrive.

Bulbs of the genus *Lilium*, of which there are approximately 50 species, are like most other bulbs in giving best results if planted when received. However, as Easter lilies are forced during the entire year, it becomes necessary to provide cold-storage conditions suitable for satisfactory holding until they are wanted for planting. The bulbs should be packed in boxes in thoroughly dry soil if rooting and desiccation are to be prevented. A temperature of 35° F., with a relative humidity of 75 to 80 percent is recommended.

Tulips are usually not stored in any packing material, although the use of such material may be advantageous for long storage. Temperatures of 36° to 38° F., except for short storage, are considered rather low for tulips shipped in from the West in which the buds are already formed. The best storage temperature for shipped tulips is between 50° and 55°.
